

DataEng: Data Storage Activity

[Github Link](#)

This week you'll gain experience with various ways to load data into a Postgres database.

Make a copy of this document and use it to record your results. Store a PDF copy of the document in your git repository along with any needed code before submitting for this week.

The data set for this week is US Census data from 2015 ~~and 2017~~. The United States conducts a full census of every household every 10 years (we just finished one last year), but much of the detailed census data comes during the intervening years when the Census Bureau conducts its detailed American Community Survey (ACS) of a randomly selected sample of approximately 3.5 million households each year. The resulting data gives a more detailed view of many factors of American life and the composition of households.

[ACS Census Tract Data for 2015](#)

[ACS Census Tract Data for 2017](#) (ignore the 2017 data)

Your job is to load the 2015 data set (approximately 74000 rows each) into your database. You'll configure a postgres DBMS on a new GCP virtual machine, and then load the data five different ways, comparing the cost of each method.

We hope that you make it all the way through to the end, but regardless, use your time wisely to gain python programming experience and learn as much as you can about bulk loading of data. Note that the goal here is not to achieve the fastest load times. Instead, your goal should be to gain knowledge about how a data storage server (such as PostgreSQL) works and why various data loading approaches produce differing performance results.

Submit: [In-class Activity Submission Form](#)

A. Configure Your Database

1. Create a new GCP virtual machine for this week's work (medium size or larger).
2. Follow the steps listed in the [Installing and Configuring and PostgreSQL server](#) instructions provided for project assignment #2. To keep things separate from your project work we suggest you use a separate vm, separate database name, separate user name, etc. Then each/all of these can then be updated or deleted whenever you need without affecting your project.

3. Also the following commands will help to configure the python module “psycopg2” which you will use to connect to your postgres database:

```
sudo apt install python3 python3-dev python3-venv  
sudo apt-get install python3-pip  
pip3 install psycopg2-binary
```

B. Connect to Database and Create Your Main Data Table

1. Copy/upload your data to your VM and uncompress it
2. Create a small test sample by running a linux command similar to the following. The small test sample will help you to quickly test any code that you write before running your code with the full dataset.

```
head -1 acs2015_census_tract_data.csv > Oregon2015.csv  
grep Oregon acs2015_census_tract_data.csv >> Oregon2015.csv
```

The first command copies the headers to the sample file and the second command appends all of the Oregon 2015 data to the sample file. This should produce a file with approximately 800 records which is a bit more than 1% of the 2015 data set.

3. Write a python program that connects to your postgres database and creates your main census data table. Start with this example code: [load_inserts.py](#). If you want to run load_inserts.py, then run it with -d <data file> -c -y 2015 Note that you must input a year value because the census data does not explicitly include the calendar year within each data file.

C. Baseline - Simple INSERT

The tried and true SQL command [INSERT INTO ...](#) is the most basic way to insert data into a SQL database, and often it is the best choice for small amounts of data, production databases and other situations in which you need to maintain performance and reliability of the updated table.

The load_inserts.py program shows how to use simple INSERTs to load data into a database. It is possibly the slowest way to load large amounts of data. For me, it takes approximately 1 second for the Oregon sample and nearly 120 seconds for the full acs 2015 data set.

Take the program and try it with both the Oregon sample and the full data sets. Fill in the appropriate table rows below.

D. The Effects of Indexes and Constraints

You might notice that the CensusData table has a composite Primary Key constraint and an additional index on the state name column. Indexes and constraints are helpful for query performance, but do not work well for load performance.

Try delaying the creation of these constraints/indexes until after the data set is loaded. Enter the resulting load time into the results table. Did this technique improve load performance?

Yes. This technique of dropping the indexes has improved the load performance, as there is no need of updating the index for each and every row.

E. The Effects of Logging

By default, RDBMS tables incur overheads of write-ahead logging (WAL) such that the database logs extra metadata about each update to the table and uses that WAL data to recover the contents of the table in case of RDBMS crash. This is a great feature but can get in your way when trying to bulk load data into the database.

Try loading to a “staging” table, a table that is [declared as UNLOGGED](#). This staging table should have no constraints or indexes. Then use a SQL query to append the staging data to the main CensusData table.

By the way, you might have noticed that the load_inserts.py program sets autocommit=True on the database connection. This makes loaded data available to DB queries immediately after each insert. But it also implies a great amount of transaction overhead. It also allows readers of the database to view an incomplete set of data during the load. How does load performance change if you do not set autocommit=True and instead explicitly commit all of the loaded data within a transaction?

Setting autocommit = False, elapsed time = 15.31 sec

With autocommit = True, elapsed time = 17.24 sec

For data loading, compared to the normal simple inserts, unlogged tables with no indexes is way faster.

F. Temp Tables and Memory Tuning

Next compare the above approach with loading the data to [a temporary table](#) (and copying from the temporary table to the CensusData table). Which approach works best for you.

The amount of memory used for temporary tables is default configured to only 8MB. Your VM has enough memory to allocate much more memory to temporary tables. Try allocating 256 MB (or more) to temporary tables. So update the [temp_buffers parameter](#) to allow the database to use more memory for your temporary table. Rerun your load experiments. Did it make a difference?

SET temp_buffers = '256MB'; elapsed time = 14.28 seconds

With default configuration to 8MB, elapsed time = 14.49 seconds

I see no difference.

G. Batching

So far our load performance has been held back by the fact we are using individuals calls to the DBMS. As with many Computer Systems situations we can improve performance by batching operations. [Haki Benita's great article about fast loading to Postgres](#) notes that use of psycopg2's execute_batch() method can increase load rate by up to two orders of magnitude. The blog provides sample code, time measurements and memory measurements. Adapt his code to your case, rerun your experiments and note your results in the table below.

Code is added to github – loadInserts_batch.py

H. Built In Facility (copy_from)

The number one rule of bulk loading is to pay attention to the native facilities provided by the DBMS system implementers. As we saw with Joyo Victor's presentation last week, the DBMS vendors often put great effort into providing purpose-build loading mechanisms that achieve great speed and scalability.

With a simple, one-server Postgres database, that facility is known as COPY, \copy, or for python programmers [copy_from](#). Haki Benita's blog shows how to use copy_from to achieve another order of magnitude in load performance. Adapt Haki's code to your case, rerun your experiments and note your results in the table.

Code is added to github – [loadInserts_copyfrom.py](#)

I. Results

Use this table to present your results. We are not asking you to do a sophisticated performance analysis here with multiple runs, warmup time, etc. Instead, do a rough measurement using timing code similar to what you see in the `load_inserts.py` code. Record your results in the following table.

Method	Code Link	acs2015
Simple inserts	load_inserts.py	118.7 seconds
Drop Indexes and Constraints	loadInserts_dropindexes.py	98.6 seconds
Use UNLOGGED table	loadInserts_unlog.py	15.31 seconds
Temp Table with memory tuning	loadInserts temptable.py	14.28 seconds
Batching	loadInserts_batch.py	10.36 seconds
copy_from	loadInserts_copyfromm.py	0.7255 seconds

J. Observations

Use this section to record any observations about the various methods/techniques that you used for bulk loading of the USA Census data. Did you learn anything about how and RDBMS functions and why various loading approaches produce varying performance results?

Observations about various methods/techniques used for bulk loading –

- **Technique of dropping the indexes has improved the load performance, as there is no need of updating the index for each and every row.**
- **For data loading, compared to the normal simple inserts, unlogged tables with no indexes are way faster.**
- **Using temp tables, SET temp_buffers = '256MB'; elapsed time = 14.28 seconds With default configuration to 8MB, elapsed time = 14.49 seconds. Even though, configuration varies there is no difference in execution time of loading the data**

Geetha Madhuri Chittuluri

- **Batching is also one of the best technique with fast execution time to load large datafiles**
- **Overall, I see copy_from() method is the best technique to load any large datafile and get done with the execution within milli seconds.**

Learnt how to do effective data loading using different techniques and gained much knowledge in exploring different techniques and how to write code effectively and how/what to do for quick execution in better and most effective ways.
